Common code for CTANGLE and CWEAVE

(Version 4.3)

1.   Introduction.   This file contains code common to both `CTANGLE` and `CWEAVE`, which roughly concerns the following problems: character uniformity, input routines, error handling and parsing of command line. We have tried to concentrate in this file all the system dependencies, so as to maximize portability.

In the texts below we will sometimes use `CWEB` to refer to either of the two component programs, if no confusion can arise.

The file begins with a few basic definitions.

⟨ Include files 3 ⟩
⟨ Preprocessor definitions ⟩
⟨ Common code for `CWEAVE` and `CTANGLE` 2 ⟩
⟨ Global variables 18 ⟩
⟨ Predeclaration of procedures 7 ⟩

2.   The details will be filled in due course. The interface of this module is included first. It is also used by the main programs.

First comes general stuff:

#**define** *ctangle* *false*
#**define** *cweave* *true*

⟨ Common code for `CWEAVE` and `CTANGLE` 2 ⟩ ≡
  typedef bool boolean;
  typedef uint8_t eight_bits;
  typedef uint16_t sixteen_bits;
  extern boolean *program*;   /∗ `CWEAVE` or `CTANGLE`? ∗/
  extern int *phase*;   /∗ which phase are we in? ∗/

See also sections 4, 5, 6, 8, 9, 11, 13, and 14.

This code is used in section 1.

3.   Interface to the standard C library:

⟨ Include files 3 ⟩ ≡
#**include** `<ctype.h>`   /∗ definition of *isalpha*, *isdigit* and so on ∗/
#**include** `<stdbool.h>`   /∗ definition of **bool**, *true* and *false* ∗/
#**include** `<stddef.h>`   /∗ definition of **ptrdiff_t** ∗/
#**include** `<stdint.h>`   /∗ definition of **uint8_t** and **uint16_t** ∗/
#**include** `<stdlib.h>`   /∗ definition of *getenv* and *exit* ∗/
#**include** `<stdio.h>`   /∗ definition of *printf* and friends ∗/
#**include** `<string.h>`   /∗ definition of *strlen*, *strcmp* and so on ∗/

This code is used in section 1.

4.   Code related to the character set:

#**define** *and_and* °*4*   /∗ '`&&`'; corresponds to MIT's ∧ ∗/
#**define** *lt_lt* °*20*   /∗ '`<<`'; corresponds to MIT's ⊂ ∗/
#**define** *gt_gt* °*21*   /∗ '`>>`'; corresponds to MIT's ⊃ ∗/
#**define** *plus_plus* °*13*   /∗ '`++`'; corresponds to MIT's ↑ ∗/
#**define** *minus_minus* °*1*   /∗ '`--`'; corresponds to MIT's ↓ ∗/
#**define** *minus_gt* °*31*   /∗ '`->`'; corresponds to MIT's → ∗/
#**define** *non_eq* °*32*   /∗ '`!=`'; corresponds to MIT's ≠ ∗/
#**define** *lt_eq* °*34*   /∗ '`<=`'; corresponds to MIT's ≤ ∗/
#**define** *gt_eq* °*35*   /∗ '`>=`'; corresponds to MIT's ≥ ∗/
#**define** *eq_eq* °*36*   /∗ '`==`'; corresponds to MIT's ≡ ∗/
#**define** *or_or* °*37*   /∗ '`||`'; corresponds to MIT's ∨ ∗/
#**define** *dot_dot_dot* °*16*   /∗ '`...`'; corresponds to MIT's ∞ ∗/
#**define** *colon_colon* °*6*   /∗ '`::`'; corresponds to MIT's ∈ ∗/
#**define** *period_ast* °*26*   /∗ '`.*`'; corresponds to MIT's ⊗ ∗/
#**define** *minus_gt_ast* °*27*   /∗ '`->*`'; corresponds to MIT's ⇆ ∗/

#**define** *compress*(*c*) **if** (*loc*++ ≤ *limit*) **return** *c*

⟨ Common code for `CWEAVE` and `CTANGLE` 2 ⟩ +≡
  extern char *section_text*[ ];   /∗ text being sought for ∗/
  extern char ∗*section_text_end*;   /∗ end of *section_text* ∗/
  extern char ∗*id_first*;   /∗ where the current identifier begins in the buffer ∗/
  extern char ∗*id_loc*;   /∗ just after the current identifier in the buffer ∗/

5.   Code related to input routines:

#**define** *xisalpha*(*c*) (*isalpha*((**eight_bits**)(*c*)) ∧ ((**eight_bits**)(*c*) < °*200*))
#**define** *xisdigit*(*c*) (*isdigit*((**eight_bits**)(*c*)) ∧ ((**eight_bits**)(*c*) < °*200*))
#**define** *xisspace*(*c*) (*isspace*((**eight_bits**)(*c*)) ∧ ((**eight_bits**)(*c*) < °*200*))
#**define** *xislower*(*c*) (*islower*((**eight_bits**)(*c*)) ∧ ((**eight_bits**)(*c*) < °*200*))
#**define** *xisupper*(*c*) (*isupper*((**eight_bits**)(*c*)) ∧ ((**eight_bits**)(*c*) < °*200*))
#**define** *xisxdigit*(*c*) (*isxdigit*((**eight_bits**)(*c*)) ∧ ((**eight_bits**)(*c*) < °*200*))
#**define** *isxalpha*(*c*) ((*c*) ≡ '`_`' ∨ (*c*) ≡ '`$`')   /∗ non-alpha characters allowed in identifier ∗/
#**define** *ishigh*(*c*) ((**eight_bits**)(*c*) > °*177*)

⟨ Common code for `CWEAVE` and `CTANGLE` 2 ⟩ +≡
  extern char *buffer*[ ];   /∗ where each line of input goes ∗/
  extern char ∗*buffer_end*;   /∗ end of *buffer* ∗/
  extern char ∗*loc*;   /∗ points to the next character to be read from the buffer ∗/
  extern char ∗*limit*;   /∗ points to the last character in the buffer ∗/

6.   Code related to file handling:

   format *line* *x*   /∗ make *line* an unreserved word ∗/

#**define** *max_include_depth* 10

       /∗ maximum number of source files open simultaneously, not counting the change file ∗/

#**define** *max_file_name_length* 1024

#**define** *cur_file* *file*[*include_depth*]   /∗ current file ∗/

#**define** *cur_file_name* *file_name*[*include_depth*]   /∗ current file name ∗/

#**define** *cur_line* *line*[*include_depth*]   /∗ number of current line in current file ∗/

#**define** *web_file* *file*[0]   /∗ main source file ∗/

#**define** *web_file_name* *file_name*[0]   /∗ main source file name ∗/

⟨ Common code for CWEAVE and CTANGLE 2 ⟩ +≡

  extern int *include_depth*;   /∗ current level of nesting ∗/

  extern FILE ∗*file*[ ];   /∗ stack of non-change files ∗/

  extern FILE ∗*change_file*;   /∗ change file ∗/

  extern char *file_name*[ ][*max_file_name_length*];   /∗ stack of non-change file names ∗/

  extern char *change_file_name*[ ];   /∗ name of change file ∗/

  extern int *line*[ ];   /∗ number of current line in the stacked files ∗/

  extern int *change_line*;   /∗ number of current line in change file ∗/

  extern int *change_depth*;   /∗ where @y originated during a change ∗/

  extern boolean *input_has_ended*;   /∗ if there is no more input ∗/

  extern boolean *changing*;   /∗ if the current line is from *change_file* ∗/

  extern boolean *web_file_open*;   /∗ if the web file is being read ∗/

7.   ⟨ Predeclaration of procedures 7 ⟩ ≡

  extern boolean *get_line*(**void**);   /∗ inputs the next line ∗/

  extern void *check_complete*(**void**);   /∗ checks that all changes were picked up ∗/

  extern void *reset_input*(**void**);   /∗ initialize to read the web file and change file ∗/

See also sections 10, 12, 15, 24, 28, 33, 55, 64, and 76.

This code is used in section 1.

8.   Code related to section numbers:

⟨ Common code for CWEAVE and CTANGLE 2 ⟩ +≡

  extern sixteen_bits *section_count*;   /∗ the current section number ∗/

  extern boolean *changed_section*[ ];   /∗ is the section changed? ∗/

  extern boolean *change_pending*;   /∗ is a decision about change still unclear? ∗/

  extern boolean *print_where*;   /∗ tells CTANGLE to print line and file info ∗/

9.   Code related to identifier and section name storage:

#**define** *length*(*c*) (**size_t**)((*c* + 1)→*byte_start* − (*c*)→*byte_start*)   /∗ the length of a name ∗/
#**define** *print_id*(*c*) *term_write*((*c*)→*byte_start*, *length*((*c*)))   /∗ print identifier ∗/
#**define** *llink link*   /∗ left link in binary search tree for section names ∗/
#**define** *rlink dummy.Rlink*   /∗ right link in binary search tree for section names ∗/
#**define** *root name_dir*→*rlink*   /∗ the root of the binary search tree for section names ∗/

⟨ Common code for CWEAVE and CTANGLE 2 ⟩ +≡
  typedef struct name_info {
    char ∗*byte_start*;   /∗ beginning of the name in *byte_mem* ∗/
    struct name_info ∗*link*;
    union {
      struct name_info ∗*Rlink*;   /∗ right link in binary search tree for section names ∗/
      char *Ilk*;   /∗ used by identifiers in CWEAVE only ∗/
    } *dummy*;
    void ∗*equiv_or_xref*;   /∗ info corresponding to names ∗/
  } **name_info**;   /∗ contains information about an identifier or section name ∗/
  typedef name_info ∗**name_pointer**;   /∗ pointer into array of **name_info**s ∗/
  typedef name_pointer ∗**hash_pointer**;
  extern char *byte_mem*[ ];   /∗ characters of names ∗/
  extern char ∗*byte_mem_end*;   /∗ end of *byte_mem* ∗/
  extern char ∗*byte_ptr*;   /∗ first unused position in *byte_mem* ∗/
  extern name_info *name_dir*[ ];   /∗ information about names ∗/
  extern name_pointer *name_dir_end*;   /∗ end of *name_dir* ∗/
  extern name_pointer *name_ptr*;   /∗ first unused position in *name_dir* ∗/
  extern name_pointer *hash*[ ];   /∗ heads of hash lists ∗/
  extern hash_pointer *hash_end*;   /∗ end of *hash* ∗/
  extern hash_pointer *h*;   /∗ index into hash-head array ∗/

10.   ⟨ Predeclaration of procedures 7 ⟩ +≡
  extern boolean *names_match*(**name_pointer**, **const char** ∗, **size_t**, **eight_bits**);
  extern name_pointer *id_lookup*(**const char** ∗, **const char** ∗, **char**);
    /∗ looks up a string in the identifier table ∗/
  extern name_pointer *section_lookup*(**char** ∗, **char** ∗, **boolean**);   /∗ finds section name ∗/
  extern void *init_node*(**name_pointer**);
  extern void *init_p*(**name_pointer**, **eight_bits**);
  extern void *print_prefix_name*(**name_pointer**);
  extern void *print_section_name*(**name_pointer**);
  extern void *sprint_section_name*(**char** ∗, **name_pointer**);

11.   Code related to error handling:

#**define** *spotless* 0   /∗ *history* value for normal jobs ∗/
#**define** *harmless_message* 1   /∗ *history* value when non-serious info was printed ∗/
#**define** *error_message* 2   /∗ *history* value when an error was noted ∗/
#**define** *fatal_message* 3   /∗ *history* value when we had to stop prematurely ∗/
#**define** *mark_harmless* **if** (*history* ≡ *spotless*) *history* ← *harmless_message*
#**define** *mark_error history* ← *error_message*
#**define** *confusion*(*s*) *fatal*("!␣This␣can't␣happen:␣", *s*)

⟨ Common code for CWEAVE and CTANGLE 2 ⟩ +≡
  extern int *history*;   /∗ indicates how bad this run was ∗/

12.   ⟨ Predeclaration of procedures 7 ⟩ +≡
  extern int *wrap_up*(**void**);   /∗ indicate *history* and exit ∗/
  extern void *err_print*(**const char** ∗);   /∗ print error message and context ∗/
  extern void *fatal*(**const char** ∗, **const char** ∗);   /∗ issue error message and die ∗/
  extern void *overflow*(**const char** ∗);   /∗ succumb because a table has overflowed ∗/

13.   Code related to command line arguments:
#**define** *show_banner* *flags*['b']   /∗ should the banner line be printed? ∗/
#**define** *show_progress* *flags*['p']   /∗ should progress reports be printed? ∗/
#**define** *show_happiness* *flags*['h']   /∗ should lack of errors be announced? ∗/
#**define** *show_stats* *flags*['s']   /∗ should statistics be printed at end of run? ∗/
#**define** *make_xrefs* *flags*['x']   /∗ should cross references be output? ∗/
⟨ Common code for CWEAVE and CTANGLE 2 ⟩ +≡
  extern int *argc*;   /∗ copy of *ac* parameter to *main* ∗/
  extern char ∗∗*argv*;   /∗ copy of *av* parameter to *main* ∗/
  extern char *C_file_name*[ ];   /∗ name of *C_file* ∗/
  extern char *tex_file_name*[ ];   /∗ name of *tex_file* ∗/
  extern char *idx_file_name*[ ];   /∗ name of *idx_file* ∗/
  extern char *scn_file_name*[ ];   /∗ name of *scn_file* ∗/
  extern boolean *flags*[ ];   /∗ an option for each 7-bit code ∗/

14.   Code related to output:
#**define** *update_terminal* *fflush*(*stdout*)   /∗ empty the terminal output buffer ∗/
#**define** *new_line* *putchar*('\n')
#**define** *term_write*(*a*, *b*) *fflush*(*stdout*), *fwrite*(*a*, **sizeof**(**char**), *b*, *stdout*)
⟨ Common code for CWEAVE and CTANGLE 2 ⟩ +≡
  extern FILE ∗*C_file*;   /∗ where output of CTANGLE goes ∗/
  extern FILE ∗*tex_file*;   /∗ where output of CWEAVE goes ∗/
  extern FILE ∗*idx_file*;   /∗ where index from CWEAVE goes ∗/
  extern FILE ∗*scn_file*;   /∗ where list of sections from CWEAVE goes ∗/
  extern FILE ∗*active_file*;   /∗ currently active file for CWEAVE output ∗/

15.   The procedure that gets everything rolling:
⟨ Predeclaration of procedures 7 ⟩ +≡
  extern void *common_init*(**void**);
  extern void *print_stats*(**void**);

16.   The following parameters were sufficient in the original WEB to handle TEX, so they should be sufficient
for most applications of CWEB.
#**define** *max_bytes* 1000000   /∗ the number of bytes in identifiers, index entries, and section names ∗/
#**define** *max_toks* 1000000   /∗ number of bytes in compressed C code ∗/
#**define** *max_names* 10239
          /∗ number of identifiers, strings, section names; must be less than 10240 ∗/
#**define** *max_sections* 4000   /∗ greater than the total number of sections ∗/
#**define** *max_texts* 10239   /∗ number of replacement texts, must be less than 10240 ∗/
#**define** *longest_name* 10000
          /∗ file and section names and section texts shouldn't be longer than this ∗/
#**define** *stack_size* 500   /∗ number of simultaneous levels of macro expansion ∗/
#**define** *buf_size* 1000   /∗ maximum length of input line, plus one ∗/
#**define** *long_buf_size* (*buf_size* + *longest_name*)   /∗ for CWEAVE ∗/

17.   End of `COMMON` interface.

18.   In certain cases `CTANGLE` and `CWEAVE` should do almost, but not quite, the same thing. In these cases we've written common code for both, differentiating between the two by means of the global variable *program*.

⟨ Global variables 18 ⟩ ≡
   boolean *program*;   /∗ `CWEAVE` or `CTANGLE`? ∗/

See also sections 19, 21, 22, 25, 26, 37, 43, 44, 46, 65, 73, and 83.

This code is used in section 1.

19.   `CWEAVE` operates in three phases: First it inputs the source file and stores cross-reference data, then it inputs the source once again and produces the TEX output file, and finally it sorts and outputs the index. Similarly, `CTANGLE` operates in two phases. The global variable *phase* tells which phase we are in.

⟨ Global variables 18 ⟩ +≡
   int *phase*;   /∗ which phase are we in? ∗/

20.   There's an initialization procedure that gets both `CTANGLE` and `CWEAVE` off to a good start. We will fill in the details of this procedure later.

   void *common_init*(**void**)
   {
     ⟨ Initialize pointers 45 ⟩
     ⟨ Set the default options common to `CTANGLE` and `CWEAVE` 74 ⟩
     ⟨ Scan arguments and open output files 84 ⟩
   }

21.   The character set.   `CWEB` uses the conventions of C programs found in the standard `ctype.h` header file.

A few character pairs are encoded internally as single characters, using the definitions in the interface sections above. These definitions are consistent with an extension of ASCII code originally developed at MIT and explained in Appendix C of *The TEXbook*; thus, users who have such a character set can type things like ≠ and ∧ instead of `!=` and `&&`. (However, their files will not be too portable until more people adopt the extended code.)

If the character set is not ASCII, the definitions given may conflict with existing characters; in such cases, other arbitrary codes should be substituted. The indexes to `CTANGLE` and `CWEAVE` mention every case where similar codes may have to be changed in order to avoid character conflicts. Look for the entry "ASCII code dependencies" in those indexes.

⟨ Global variables 18 ⟩ +≡
    char *section_text*[*longest_name* + 1];   /∗ text being sought for ∗/
    char ∗*section_text_end* ← *section_text* + *longest_name*;   /∗ end of *section_text* ∗/
    char ∗*id_first*;   /∗ where the current identifier begins in the buffer ∗/
    char ∗*id_loc*;   /∗ just after the current identifier in the buffer ∗/

22. Input routines.   The lowest level of input to the CWEB programs is performed by *input_ln*, which must be told which file to read from. The return value of *input_ln* is *true* if the read is successful and *false* if not (generally this means the file has ended). The conventions of TEX are followed; i.e., the characters of the next line of the file are copied into the *buffer* array, and the global variable *limit* is set to the first unoccupied position. Trailing blanks are ignored. The value of *limit* must be strictly less than *buf_size*, so that *buffer*[*buf_size* − 1] is never filled.

   Since *buf_size* is strictly less than *long_buf_size*, some of CWEB's routines use the fact that it is safe to refer to ∗(*limit* + 2) without overstepping the bounds of the array.

⟨ Global variables 18 ⟩ +≡
   char *buffer*[*long_buf_size*];   /∗ where each line of input goes ∗/
   char ∗*buffer_end* ← *buffer* + *buf_size* − 2;   /∗ end of *buffer* ∗/
   char ∗*loc* ← *buffer*;   /∗ points to the next character to be read from the buffer ∗/
   char ∗*limit* ← *buffer*;   /∗ points to the last character in the buffer ∗/

23.   In the unlikely event that your standard I/O library does not support *feof*, *getc*, and *ungetc* you may have to change things here.

   static boolean *input_ln*(/∗ copies a line into *buffer* or returns *false* ∗/
       FILE ∗*fp*)   /∗ what file to read from ∗/
   {
      register int *c* ← EOF;   /∗ character read; initialized so some compilers won't complain ∗/
      register char ∗*k*;   /∗ where next character goes ∗/
      if (*feof*(*fp*)) **return** *false*;   /∗ we have hit end-of-file ∗/
      limit ← *k* ← *buffer*;   /∗ beginning of buffer ∗/
      while (*k* ≤ *buffer_end* ∧ (*c* ← *getc*(*fp*)) ≠ EOF ∧ *c* ≠ '\n')
         if ((∗(*k*++) ← *c*) ≠ '␣') *limit* ← *k*;
      if (*k* > *buffer_end*)
         if ((*c* ← *getc*(*fp*)) ≠ EOF ∧ *c* ≠ '\n') {
            ungetc(*c*, *fp*);
            loc ← *buffer*;
            err_print("!␣Input␣line␣too␣long");
         }
      if (*c* ≡ EOF ∧ *limit* ≡ *buffer*) **return** *false*;   /∗ there was nothing after the last newline ∗/
      return *true*;
   }

24.   ⟨ Predeclaration of procedures 7 ⟩ +≡   **static boolean** *input_ln*(**FILE** ∗);

25.   Now comes the problem of deciding which file to read from next. Recall that the actual text that CWEB should process comes from two streams: a *web_file*, which can contain possibly nested include commands @i, and a *change_file*, which might also contain includes. The *web_file* together with the currently open include files form a stack *file*, whose names are stored in a parallel stack *file_name*. The boolean *changing* tells whether or not we're reading from the *change_file*.

   The line number of each open file is also kept for error reporting and for the benefit of CTANGLE.

⟨ Global variables 18 ⟩ +≡
   int *include_depth*;   /∗ current level of nesting ∗/
   FILE ∗*file*[*max_include_depth*];   /∗ stack of non-change files ∗/
   FILE ∗*change_file*;   /∗ change file ∗/
   char *file_name*[*max_include_depth*][*max_file_name_length*];   /∗ stack of non-change file names ∗/
   char *change_file_name*[*max_file_name_length*];   /∗ name of change file ∗/
   static char *alt_web_file_name*[*max_file_name_length*];   /∗ alternate name to try ∗/
   int *line*[*max_include_depth*];   /∗ number of current line in the stacked files ∗/
   int *change_line*;   /∗ number of current line in change file ∗/
   int *change_depth*;   /∗ where @y originated during a change ∗/
   boolean *input_has_ended*;   /∗ if there is no more input ∗/
   boolean *changing*;   /∗ if the current line is from *change_file* ∗/
   boolean *web_file_open* ← *false*;   /∗ if the web file is being read ∗/

26.   When *changing* ≡ *false*, the next line of *change_file* is kept in *change_buffer*, for purposes of comparison with the next line of *cur_file*. After the change file has been completely input, we set *change_limit* ← *change_buffer*, so that no further matches will be made.

   Here's a shorthand expression for inequality between the two lines:

#**define** *lines_dont_match* (*change_limit* − *change_buffer* ≠ *limit* − *buffer*
             ∨ *strncmp*(*buffer*, *change_buffer*, (**size_t**)(*limit* − *buffer*)))

⟨ Global variables 18 ⟩ +≡
   static char *change_buffer*[*buf_size*];   /∗ next line of *change_file* ∗/
   static char ∗*change_limit*;   /∗ points to the last character in *change_buffer* ∗/

27.   Procedure *prime_the_change_buffer* sets *change_buffer* in preparation for the next matching operation. Since blank lines in the change file are not used for matching, we have (*change_limit* ≡ *change_buffer* ∧ ¬*changing*) if and only if the change file is exhausted. This procedure is called only when *changing* is *true*; hence error messages will be reported correctly.

   static void *prime_the_change_buffer*(**void**)
   {
     change_limit ← *change_buffer*;   /∗ this value is used if the change file ends ∗/
     ⟨ Skip over comment lines in the change file; **return** if end of file 29 ⟩
     ⟨ Skip to the next nonblank line; **return** if end of file 30 ⟩
     ⟨ Move *buffer* and *limit* to *change_buffer* and *change_limit* 31 ⟩
   }

28.   ⟨ Predeclaration of procedures 7 ⟩ +≡ **static void** *prime_the_change_buffer*(**void**);

29.   While looking for a line that begins with `@x` in the change file, we allow lines that begin with `@`, as long as they don't begin with `@y`, `@z`, or `@i` (which would probably mean that the change file is fouled up).

⟨ Skip over comment lines in the change file; **return** if end of file 29 ⟩ ≡

```
  while (true) {
    change_line ++;
    if (¬input_ln(change_file)) return;
    if (limit < buffer + 2) continue;
    if (buffer[0] ≠ '@') continue;
    if (xisupper(buffer[1])) buffer[1] ← tolower((eight_bits) buffer[1]);
    if (buffer[1] ≡ 'x') break;
    if (buffer[1] ≡ 'y' ∨ buffer[1] ≡ 'z' ∨ buffer[1] ≡ 'i') {
      loc ← buffer + 2;
      err_print("! Missing @x in change file");
    }
  }
```

This code is used in section 27.

30.   Here we are looking at lines following the `@x`.

⟨ Skip to the next nonblank line; **return** if end of file 30 ⟩ ≡

```
  do {
    change_line ++;
    if (¬input_ln(change_file)) {
      err_print("! Change file ended after @x");
      return;
    }
  } while (limit ≡ buffer);
```

This code is used in section 27.

31.   ⟨ Move *buffer* and *limit* to *change_buffer* and *change_limit* 31 ⟩ ≡

```
  {
    change_limit ← change_buffer + (ptrdiff_t)(limit − buffer);
    strncpy(change_buffer, buffer, (size_t)(limit − buffer + 1));
  }
```

This code is used in sections 27 and 32.

32.   The following procedure is used to see if the next change entry should go into effect; it is called only
when *changing* is *false*. The idea is to test whether or not the current contents of *buffer* matches the current
contents of *change_buffer*. If not, there's nothing more to do; but if so, a change is called for: All of the
text down to the @y is supposed to match. An error message is issued if any discrepancy is found. Then the
procedure prepares to read the next line from *change_file*.

When a match is found, the current section is marked as changed unless the first line after the @x and
after the @y both start with either '@*' or '@␣' (possibly preceded by whitespace).

This procedure is called only when *buffer* < *limit*, i.e., when the current line is nonempty.

#**define** *if_section_start_make_pending*(*b*)

　　　fatal("!␣Cannot␣open␣input␣file␣", *web_file_name*);
　}
　web_file_open ← *true*;
　if ((*change_file* ← *fopen*(*change_file_name*, "r")) ≡ Λ)
　　fatal("!␣Cannot␣open␣change␣file␣", *change_file_name*);
This code is used in section 35.

37.   The *get_line* procedure is called when *loc* > *limit*; it puts the next line of merged input into the buffer and updates the other variables appropriately. A space is placed at the right end of the line. This procedure returns ¬*input_has_ended* because we often want to check the value of that variable after calling the procedure.

If we've just changed from the *cur_file* to the *change_file*, or if the *cur_file* has changed, we tell CTANGLE to print this information in the C file by means of the *print_where* flag.

⟨Global variables 18⟩ +≡

        }
    }
}
```
This code is used in section 38.

42. At the end of the program, we will tell the user if the change file had a line that didn't match any relevant line in *web_file*.

```
void check_complete(void)
{
    if (change_limit ≠ change_buffer) {        /* changing is false */
        strncpy(buffer, change_buffer, (size_t)(change_limit − change_buffer + 1));
        limit ← buffer + (ptrdiff_t)(change_limit − change_buffer);
        changing ← true;
        change_depth ← include_depth;
        loc ← buffer;
        err_print("! Change file entry did not match");
    }
}
```

43. Storage of names and strings. Both CWEAVE and CTANGLE store identifiers, section names and other strings in a large array of **char**s, called *byte_mem*. Information about the names is kept in the array *name_dir*, whose elements are structures of type **name_info**, containing a pointer into the *byte_mem* array (the address where the name begins) and other data. A **name_pointer** variable is a pointer into *name_dir*. You find the complete layout of **name_info** in the interface sections above.

The actual sequence of characters in the name pointed to by a **name_pointer** p appears in positions $p{\rightarrow}byte\_start$ to $(p+1){\rightarrow}byte\_start - 1$, inclusive.

The names of identifiers are found by computing a hash address h and then looking at strings of bytes signified by the **name_pointer**s $hash[h]$, $hash[h]{\rightarrow}link$, $hash[h]{\rightarrow}link{\rightarrow}link$, ..., until either finding the desired name or encountering the null pointer.

The names of sections are stored in *byte_mem* together with the identifier names, but a hash table is not used for them because CTANGLE needs to be able to recognize a section name when given a prefix of that name. A conventional binary search tree is used to retrieve section names, with fields called *llink* and *rlink* (where *llink* takes the place of *link*). The root of this tree is stored in *name_dir{\rightarrow}rlink*; this will be the only information in *name_dir*[0].

Since the space used by *rlink* has a different function for identifiers than for section names, we declare it as a **union**.

The last component of **name_info** is different for CTANGLE and CWEAVE. In CTANGLE, if p is a pointer to a section name, $p{\rightarrow}equiv$ is a pointer to its replacement text, an element of the array *text_info*. In CWEAVE, on the other hand, if p points to an identifier, $p{\rightarrow}xref$ is a pointer to its list of cross-references, an element of the array *xmem*. The make-up of *text_info* and *xmem* is discussed in the CTANGLE and CWEAVE source files, respectively; here we just declare a common field *equiv_or_xref* as a pointer to **void**.

⟨ Global variables 18 ⟩ +≡
  char *byte_mem*[*max_bytes*];   /∗ characters of names ∗/
  char ∗*byte_mem_end* ← *byte_mem* + *max_bytes* − 1;   /∗ end of *byte_mem* ∗/
  name_info *name_dir*[*max_names*];   /∗ information about names ∗/
  name_pointer *name_dir_end* ← *name_dir* + *max_names* − 1;   /∗ end of *name_dir* ∗/

44. The first unused position in *byte_mem* and *name_dir* is kept in *byte_ptr* and *name_ptr*, respectively. Thus we usually have *name_ptr{\rightarrow}byte_start* ≡ *byte_ptr*, and certainly we want to keep *name_ptr* ≤ *name_dir_end* and *byte_ptr* ≤ *byte_mem_end*.

⟨ Global variables 18 ⟩ +≡
  char ∗*byte_ptr*;   /∗ first unused position in *byte_mem* ∗/
  name_pointer *name_ptr*;   /∗ first unused position in *name_dir* ∗/

45. ⟨ Initialize pointers 45 ⟩ ≡
  name_dir{\rightarrow}byte_start ← *byte_ptr* ← *byte_mem*;   /∗ position zero in both arrays ∗/
  name_ptr ← *name_dir* + 1;   /∗ *name_dir*[0] will be used only for error recovery ∗/
  name_ptr{\rightarrow}byte_start ← *byte_mem*;   /∗ this makes name 0 of length zero ∗/
  root ← Λ;   /∗ the binary search tree starts out with nothing in it ∗/

See also section 47.

This code is used in section 20.

46.   The hash table itself consists of *hash_size* entries of type **name_pointer**, and is updated by the *id_lookup* procedure, which finds a given identifier and returns the appropriate **name_pointer**. The matching is done by the function *names_match*, which is slightly different in CWEAVE and CTANGLE. If there is no match for the identifier, it is inserted into the table.

#**define** *hash_size* 8501   /∗ should be prime ∗/

⟨ Global variables 18 ⟩ +≡
   name_pointer *hash*[*hash_size*];   /∗ heads of hash lists ∗/
   hash_pointer *hash_end* ← *hash* + *hash_size* − 1;   /∗ end of *hash* ∗/
   hash_pointer *h*;   /∗ index into hash-head array ∗/

47.   Initially all the hash lists are empty.

⟨ Initialize pointers 45 ⟩ +≡
   for (*h* ← *hash*; *h* ≤ *hash_end*; ∗*h*++ ← Λ) ;

48.   Here is the main procedure for finding identifiers:
   name_pointer *id_lookup*(/∗ looks up a string in the identifier table ∗/
      const char ∗*first*,   /∗ first character of string ∗/
      const char ∗*last*,   /∗ last character of string plus one ∗/
      char *t*)   /∗ the *ilk*; used by CWEAVE only ∗/
   {
      const char ∗*i* ← *first*;   /∗ position in *buffer* ∗/
      int *h*;   /∗ hash code ∗/
      int *l*;   /∗ length of the given identifier ∗/
      name_pointer *p*;   /∗ where the identifier is being sought ∗/
      if (*last* ≡ Λ)
         for (*last* ← *first*; ∗*last* ≠ '\0'; *last*++) ;
      l ← (**int**)(*last* − *first*);   /∗ compute the length ∗/
      ⟨ Compute the hash code *h* 49 ⟩
      ⟨ Compute the name location *p* 50 ⟩
      if (*p* ≡ *name_ptr*) ⟨ Enter a new name into the table at position *p* 51 ⟩
      return *p*;
   }

49.   A simple hash code is used: If the sequence of character codes is $c_1 c_2 \ldots c_n$, its hash value will be

$$(2^{n-1}c_1 + 2^{n-2}c_2 + \cdots + c_n) \bmod \textit{hash\_size}.$$

⟨ Compute the hash code *h* 49 ⟩ ≡
   h ← (**eight_bits**) ∗*i*;
   while (++*i* < *last*) *h* ← (*h* + *h* + (**int**)((**eight_bits**) ∗*i*)) % *hash_size*;
This code is used in section 48.

50.   If the identifier is new, it will be placed in position $p \leftarrow name\_ptr$, otherwise p will point to its existing location.

⟨ Compute the name location p 50 ⟩ ≡
  $p \leftarrow hash[h]$;
  while $(p \wedge \neg names\_match(p, first, l, t))$ $p \leftarrow p\text{-}link$;
  if $(p \equiv \Lambda)$ {
    $p \leftarrow name\_ptr$;   /∗ the current identifier is new ∗/
    $p\text{-}link \leftarrow hash[h]$;
    $hash[h] \leftarrow p$;   /∗ insert p at beginning of hash list ∗/
  }

This code is used in section 48.

51.   The information associated with a new identifier must be initialized in a slightly different way in CWEAVE than in CTANGLE; hence the $init\_p$ procedure.

⟨ Enter a new name into the table at position p 51 ⟩ ≡
  {
    if $(byte\_ptr + l > byte\_mem\_end)$ $overflow($"byte␣memory"$)$;
    if $(name\_ptr \geq name\_dir\_end)$ $overflow($"name"$)$;
    $strncpy(byte\_ptr, first, l)$;
    $(\texttt{++}name\_ptr)\text{-}byte\_start \leftarrow byte\_ptr \mathrel{+}= l$;
    $init\_p(p, t)$;
  }

This code is used in section 48.

52.   If p is a **name_pointer** variable, as we have seen, $p\text{-}byte\_start$ is the beginning of the area where the name corresponding to p is stored. However, if p refers to a section name, the name may need to be stored in chunks, because it may "grow": a prefix of the section name may be encountered before the full name. Furthermore we need to know the length of the shortest prefix of the name that was ever encountered.

    We solve this problem by inserting two extra bytes at $p\text{-}byte\_start$, representing the length of the shortest prefix, when p is a section name. Furthermore, the last byte of the name will be a blank space if p is a prefix. In the latter case, the name pointer $p + 1$ will allow us to access additional chunks of the name: The second chunk will begin at the name pointer $(p + 1)\text{-}link$, and if it too is a prefix (ending with blank) its $link$ will point to additional chunks in the same way. Null links are represented by $name\_dir$.

#**define** $first\_chunk(p)$ $((p)\text{-}byte\_start + 2)$
#**define** $prefix\_length(p)$ $(\textbf{int})((\textbf{eight\_bits}) * ((p)\text{-}byte\_start) * 256 + (\textbf{eight\_bits}) * ((p)\text{-}byte\_start + 1))$
#**define** $set\_prefix\_length(p, m)$ $(*((p)\text{-}byte\_start) \leftarrow (m)/256, *((p)\text{-}byte\_start + 1) \leftarrow (m) \% 256)$

  void $print\_section\_name($**name_pointer** $p)$
  {
    char $*ss$, $*s \leftarrow first\_chunk(p)$;
    name_pointer $q \leftarrow p + 1$;
    while $(p \neq name\_dir)$ {
      $ss \leftarrow (p + 1)\text{-}byte\_start - 1$;
      if $(*ss \equiv \text{'}\sqcup\text{'} \wedge ss \geq s)$ $p \leftarrow q\text{-}link, q \leftarrow p$;
      else $ss\texttt{++}, p \leftarrow name\_dir, q \leftarrow \Lambda$;
      $term\_write(s, (\textbf{size\_t})(ss - s))$;
      $s \leftarrow p\text{-}byte\_start$;
    }
    if (q) $term\_write($"..."$, 3)$;   /∗ complete name not yet known ∗/
  }

53.   **void** *sprint_section_name*(**char** *∗dest*, **name_pointer** *p*)
  {
     char *∗ss*, *∗s* ← *first_chunk*(*p*);
     name_pointer *q* ← *p* + 1;

  }

57. Adding a section name to the tree is straightforward if we know its parent and whether it's the *rlink* or *llink* of the parent. As a special case, when the name is the first section being added, we set the "parent" to Λ. When a section name is created, it has only one chunk, which however may be just a prefix; the full name will hopefully be unveiled later. Obviously, *prefix_length* starts out as the length of the first chunk, though it may decrease later.

  The information associated with a new node must be initialized differently in CWEAVE and CTANGLE; hence the *init_node* procedure, which is defined differently in cweave.w and ctangle.w.

```
static name_pointer add_section_name(       /* install a new node in the tree */
     name_pointer par,      /* parent of new node */
     int c,      /* right or left? */
     char *first,       /* first character of section name */
     char *last,       /* last character of section name, plus one */
     boolean ispref)       /* are we adding a prefix or a full name? */
{
   name_pointer p ← name_ptr;      /* new node */
   char *s ← first_chunk(p);
   int name_len ← (int)(last − first) + ispref;       /* length of section name */
   if (s + name_len > byte_mem_end) overflow("byte␣memory");
   if (name_ptr + 1 ≥ name_dir_end) overflow("name");
   (++name_ptr)→byte_start ← byte_ptr ← s + name_len;
   if (ispref) {
      *(byte_ptr − 1) ← '␣';
      name_len −−;
      name_ptr→link ← name_dir;
      (++name_ptr)→byte_start ← byte_ptr;
   }
   set_prefix_length(p, name_len);
   strncpy(s, first, name_len);
   p→llink ← p→rlink ← Λ;
   init_node(p);
   return par ≡ Λ ? (root ← p) : c ≡ less ? (par→llink ← p) : (par→rlink ← p);
}
```

58.
```
static void extend_section_name(name_pointer p,      /* name to be extended */
     char *first,      /* beginning of extension text */
     char *last,      /* one beyond end of extension text */
     boolean ispref)       /* are we adding a prefix or a full name? */
{
   char *s;
   name_pointer q ← p + 1;
   int name_len ← (int)(last − first) + ispref;
   if (name_ptr ≥ name_dir_end) overflow("name");
   while (q→link ≠ name_dir) q ← q→link;
   q→link ← name_ptr;
   s ← name_ptr→byte_start;
   name_ptr→link ← name_dir;
   if (s + name_len > byte_mem_end) overflow("byte␣memory");
   (++name_ptr)→byte_start ← byte_ptr ← s + name_len;
   strncpy(s, first, name_len);
   if (ispref) *(byte_ptr − 1) ← '␣';
}
```

59.   The *section_lookup* procedure is supposed to find a section name that matches a new name, installing the new name if it doesn't match an existing one. The new name is the string between *first* and *last*; a "match" means that the new name exactly equals or is a prefix or extension of a name in the tree.

> **name_pointer** *section_lookup*(/∗ find or install section name in tree ∗/
>   **char** ∗*first*, **char** ∗*last*,   /∗ first and last characters of new name ∗/
>   **boolean** *ispref*)   /∗ is the new name a prefix or a full name? ∗/
> {

>   **name_pointer** *r* ← Λ;   /∗ where a match has been found ∗/
>   **name_pointer** *par* ← Λ;   /∗ parent of *p*, if *r* is Λ; otherwise parent of *r* ∗/
>   **int** *name_len* ← (**int**)(*last* − *first*) + 1;
>
>   ⟨ Look for matches for new name among shortest prefixes, complaining if more than one is found 60 ⟩
>   ⟨ If no match found, add new name to tree 61 ⟩
>   ⟨ If one match found, check for compatibility and return match 62 ⟩
> }

60.   A legal new name matches an existing section name if and only if it matches the shortest prefix of that section name. Therefore we can limit our search for matches to shortest prefixes, which eliminates the need for chunk-chasing at this stage.

⟨ Look for matches for new name among shortest prefixes, complaining if more than one is found 60 ⟩ ≡
   while (*p*) {   /∗ compare shortest prefix of *p* with new name ∗/
      c ← *web_strcmp*(*first*, *name_len*, *first_chunk*(*p*), *prefix_length*(*p*));
      if (*c* ≡ *less* ∨ *c* ≡ *greater*) {   /∗ new name does not match *p* ∗/
         if (*r* ≡ Λ)   /∗ no previous matches have been found ∗/
            par ← *p*;
         p ← (*c* ≡ *less* ? *p*⃗*llink* : *p*⃗*rlink*);
      }
      else {   /∗ new name matches *p* ∗/
         if (*r* ≠ Λ) {   /∗ and also *r*: illegal ∗/
            fputs("\n!␣Ambiguous␣prefix:␣matches␣<", *stdout*);
            print_prefix_name(*p*);
            fputs(">\n␣and␣<", *stdout*);
            print_prefix_name(*r*);
            err_print(">");
            return *name_dir*;   /∗ the unsection ∗/
         }
         r ← *p*;   /∗ remember match ∗/
         p ← *p*⃗*llink*;   /∗ try another ∗/
         q ← *r*⃗*rlink*;   /∗ we'll get back here if the new *p* doesn't match ∗/
      }
      if (*p* ≡ Λ) *p* ← *q*, *q* ← Λ;   /∗ *q* held the other branch of *r* ∗/
   }
This code is used in section 59.

61.   ⟨ If no match found, add new name to tree 61 ⟩ ≡
   if (*r* ≡ Λ)   /∗ no matches were found ∗/
      return *add_section_name*(*par*, *c*, *first*, *last* + 1, *ispref*);
This code is used in section 59.

62. Although error messages are given in anomalous cases, we do return the unique best match when a discrepancy is found, because users often change a title in one place while forgetting to change it elsewhere.

⟨ If one match found, check for compatibility and return match 62 ⟩ ≡

    switch (*section_name_cmp*(&*first*, *name_len*, *r*)) {   /∗ compare all of *r* with new name ∗/

    case *prefix*:

      if (¬*ispref*) {

        fputs("\n!␣New␣name␣is␣a␣prefix␣of␣<", *stdout*);

        print_section_name(*r*);

        err_print(">");

      }

      else if (*name_len* < *prefix_length*(*r*)) *set_prefix_length*(*r*, *name_len*);   /∗ fall through ∗/

    case *equal*: **break**;

    case *extension*:

      print_prefix_name(*r*);

      fputs(">,\n␣which␣abbreviates␣<", *stdout*);

      print_section_name(*r*);

      err_print(">");

    }

    return *r*;

This code is used in section 59.

63.   The return codes of *section_name_cmp*, which compares a string with the full name of a section, are those of *web_strcmp* plus *bad_extension*, used when the string is an extension of a supposedly already complete section name. This function has a side effect when the comparison string is an extension: It advances the address of the first character of the string by an amount equal to the length of the known part of the section name.

   The name `@<foo...@>` should be an acceptable "abbreviation" for `@<foo@>`. If such an abbreviation comes after the complete name, there's no trouble recognizing it. If it comes before the complete name, we simply append a null chunk. This logic requires us to regard `@<foo...@>` as an "extension" of itself.

#**define** *bad_extension* 5

  static int *section_name_cmp*(**char** ∗∗*pfirst*,   /∗ pointer to beginning of comparison string ∗/

    char ∗*ss*, ∗*s* ← *first_chunk*(*r*);
    int *c* ← *less*;   /∗ comparison ∗/
    boolean *ispref*;   /∗ is chunk *r* a prefix? ∗/
    while (*true*) {
      ss ← (*r* + 1)⃗*byte_start* − 1;
      if (∗*ss* ≡ '␣' ∧ *ss* ≥ *r*⃗*byte_start*) *ispref* ← *true*, *q* ← *q*⃗*link*;
      else *ispref* ← *false*, *ss*++, *q* ← *name_dir*;
      switch (*c* ← *web_strcmp*(*first*, *len*, *s*, *ss* − *s*)) {
      case *equal*:
        if (*q* ≡ *name_dir*)
          if (*ispref*) {
            ∗*pfirst* ← *first* + (**ptrdiff_t**)(*ss* − *s*);
            return *extension*;   /∗ null extension ∗/
          }
          else return *equal*;
        else return (*q*⃗*byte_start* ≡ (*q* + 1)⃗*byte_start*) ? *equal* : *prefix*;
      case *extension*:
        if (¬*ispref*) **return** *bad_extension*;
        first += *ss* − *s*;
        if (*q* ≠ *name_dir*) {
          len −= (**int**)(*ss* − *s*);
          s ← *q*⃗*byte_start*;
          r ← *q*;
          continue;
        }
        ∗*pfirst* ← *first*;
        return *extension*;
      default: **return** *c*;
      }
    }
  }

64.   ⟨Predeclaration of procedures 7⟩ +≡ **static int** *section_name_cmp*(**char** ∗∗, **int**, **name_pointer**);

65.   Reporting errors to the user.   A global variable called *history* will contain one of four values at the end of every run: *spotless* means that no unusual messages were printed; *harmless_message* means that a message of possible interest was printed but no serious errors were detected; *error_message* means that at least one error was found; *fatal_message* means that the program terminated abnormally. The value of *history* does not influence the behavior of the program; it is simply computed for the convenience of systems that might want to use such information.

⟨ Global variables 18 ⟩ +≡
 int *history* ← *spotless*; /∗ indicates how bad this run was ∗/

66.   The command '*err_print*("!␣Error␣message")' will report a syntax error to the user, by printing the error message at the beginning of a new line and then giving an indication of where the error was spotted in the source file. Note that no period follows the error message, since the error routine will automatically supply a period. A newline is automatically supplied if the string begins with "!".

 void *err_print*(/∗ prints '.' and location of error message ∗/
  const char ∗*s*)
 {
  char ∗*k*, ∗*l*; /∗ pointers into *buffer* ∗/
  printf (∗*s* ≡ '!' ? "\n%s" : "%s", *s*);
  if (*web_file_open*) ⟨ Print error location based on input buffer 67 ⟩
  update_terminal;
  mark_error;
 }

67.   The error locations can be indicated by using the global variables *loc*, *cur_line*, *cur_file_name* and *changing*, which tell respectively the first unlooked-at position in *buffer*, the current line number, the current file, and whether the current line is from *change_file* or *cur_file*. This routine should be modified on systems whose standard text editor has special line-numbering conventions.

⟨ Print error location based on input buffer 67 ⟩ ≡
 {
  if (*changing* ∧ *include_depth* ≡ *change_depth*) *printf* (".␣(l.␣%d␣of␣change␣file)\n", *change_line*);
  else if (*include_depth* ≡ 0) *printf* (".␣(l.␣%d)\n", *cur_line*);
  else *printf* (".␣(l.␣%d␣of␣include␣file␣%s)\n", *cur_line*, *cur_file_name*);
  l ← (*loc* ≥ *limit* ? *limit* : *loc*);
  if (*l* > *buffer*) {
   for (*k* ← *buffer*; *k* < *l*; *k*++)
    if (∗*k* ≡ '\t') *putchar*('␣');
    else *putchar*(∗*k*); /∗ print the characters already read ∗/
   new_line;
   for (*k* ← *buffer*; *k* < *l*; *k*++) *putchar*('␣'); /∗ space out the next line ∗/
  }
  for (*k* ← *l*; *k* < *limit*; *k*++) *putchar*(∗*k*); /∗ print the part not yet read ∗/
  if (∗*limit* ≡ '|') *putchar*('|'); /∗ end of C text in section names ∗/
  putchar('␣'); /∗ to separate the message from future asterisks ∗/
 }
This code is used in section 66.

68. When no recovery from some error has been provided, we have to wrap up and quit as graciously as possible. This is done by calling the function *wrap_up* at the end of the code.

CTANGLE and CWEAVE have their own notions about how to print the job statistics. See the function(s) *print_stats* in the interface above and in the index.

Some implementations may wish to pass the *history* value to the operating system so that it can be used to govern whether or not other programs are started. Here, for instance, we pass the operating system a status of EXIT_SUCCESS if and only if only harmless messages were printed.

> **int** *wrap_up*(**void**)
> {
>   **if** (*show_progress*) *new_line*;
>   **if** (*show_stats*) *print_stats*();   /∗ print statistics about memory usage ∗/
>   ⟨Print the job *history* 69⟩
>   **if** (*history* > *harmless_message*) **return** EXIT_FAILURE;
>   **else return** EXIT_SUCCESS;
> }

69.   ⟨Print the job *history* 69⟩ ≡
  switch (*history*) {
  case *spotless*:
    if (*show_happiness*) *puts*("(No␣errors␣were␣found.)");
    break;
  case *harmless_message*: *puts*("(Did␣you␣see␣the␣warning␣message␣above?)");
    break;
  case *error_message*: *puts*("(Pardon␣me,␣but␣I␣think␣I␣spotted␣something␣wrong.)");
    break;
  case *fatal_message*: **default**: *puts*("(That␣was␣a␣fatal␣error,␣my␣friend.)");
  }
This code is used in section 68.

70. When there is no way to recover from an error, the *fatal* subroutine is invoked. This happens most often when *overflow* occurs.

The two parameters to *fatal* are strings that are essentially concatenated to print the final error message.

> **void** *fatal*(**const char** ∗*s*, **const char** ∗*t*)
> {
>   **if** (∗*s*) *err_print*(*s*);
>   *err_print*(*t*);
>   *history* ← *fatal_message*;
>   *exit*(*wrap_up*());
> }

71. An overflow stop occurs if CWEB's tables aren't large enough.

> **void** *overflow*(**const char** ∗*t*)
> {
>   *printf*("\n!␣Sorry,␣%s␣capacity␣exceeded", *t*);
>   *fatal*("", "");
> }

72. Sometimes the program's behavior is far different from what it should be, and CWEB prints an error message that is really for the CWEB maintenance person, not the user. In such cases the program says *confusion*("indication␣of␣where␣we␣are").

73.   Command line arguments.   The user calls `CWEAVE` and `CTANGLE` with arguments on the command line. These are either file names or flags to be turned off (beginning with `"-"`) or flags to be turned on (beginning with `"+"`). The following globals are for communicating the user's desires to the rest of the program. The various file name variables contain strings with the names of those files. Most of the 128 flags are undefined but available for future extensions.

⟨ Global variables 18 ⟩ +≡
  int *argc*;   /∗ copy of *ac* parameter to *main* ∗/
  char ∗∗*argv*;   /∗ copy of *av* parameter to *main* ∗/
  char *C_file_name*[*max_file_name_length*];   /∗ name of *C_file* ∗/
  char *tex_file_name*[*max_file_name_length*];   /∗ name of *tex_file* ∗/
  char *idx_file_name*[*max_file_name_length*];   /∗ name of *idx_file* ∗/
  char *scn_file_name*[*max_file_name_length*];   /∗ name of *scn_file* ∗/
  boolean *flags*[128];   /∗ an option for each 7-bit code ∗/

74.   The *flags* will be initially *false*. Some of them are set to *true* before scanning the arguments; if additional flags are *true* by default they should be set before calling *common_init*.

⟨ Set the default options common to `CTANGLE` and `CWEAVE` 74 ⟩ ≡
  show_banner ← *show_happiness* ← *show_progress* ← *make_xrefs* ← *true*;

This code is used in section 20.

75.   We now must look at the command line arguments and set the file names accordingly. At least one file name must be present: the CWEB file. It may have an extension, or it may omit the extension to get `".w"` or `".web"` added. The TEX output file name is formed by replacing the CWEB file name extension by `".tex"`, and the C file name by replacing the extension by `".c"`, after removing the directory name (if any).

If there is a second file name present among the arguments, it is the change file, again either with an extension or without one to get `".ch"`. An omitted change file argument means that `"/dev/null"` should be used, when no changes are desired.

If there's a third file name, it will be the output file.

static void $scan\_args($**void**$)$
{
   char $*dot\_pos$;   /* position of `'.'` in the argument */

      strcpy (*tex_file_name*, *∗argv*);
      strcpy (*C_file_name*, *∗argv*);
      if (*make_xrefs*) {   /∗ indexes will be generated ∗/
        ∗dot_pos ← 0;
        sprintf (*idx_file_name*, "%s.idx", *∗argv*);
        sprintf (*scn_file_name*, "%s.scn", *∗argv*);
      }
    }
    found_out ← *true*;
  }
This code is used in section 75.

80. **#define** *flag_change* (*∗∗argv* ≠ '−')
⟨Handle flag argument 80⟩ ≡
  for (*dot_pos* ← *∗argv* + 1; *∗dot_pos* > '\0'; *dot_pos* ++) *flags* [(**eight_bits**) *∗dot_pos*] ← *flag_change*;
This code is used in section 75.

81. ⟨Print usage error message and quit 81⟩ ≡
  {
    if (*program* ≡ *ctangle*)
      fatal ("!␣Usage:␣ctangle␣[options]␣webfile[.w]␣[{changefile[.ch]|−}␣[outfile[.c]]]\n",
        "");
    else
      fatal ("!␣Usage:␣cweave␣[options]␣webfile[.w]␣[{changefile[.ch]|−}␣[outfile[.tex]]]\n",
        "");
  }
This code is used in section 75.

82. ⟨Complain about argument length 82⟩ ≡
  fatal ("!␣Filename␣too␣long\n", *∗argv*);
This code is used in sections 77, 78, and 79.

83.   Output.   Here is the code that opens the output file:

⟨ Global variables 18 ⟩ +≡
  FILE ∗*C_file*;   /∗ where output of CTANGLE goes ∗/
  FILE ∗*tex_file*;   /∗ where output of CWEAVE goes ∗/
  FILE ∗*idx_file*;   /∗ where index from CWEAVE goes ∗/
  FILE ∗*scn_file*;   /∗ where list of sections from CWEAVE goes ∗/
  FILE ∗*active_file*;   /∗ currently active file for CWEAVE output ∗/

84.   ⟨ Scan arguments and open output files 84 ⟩ ≡
  scan_args( );
  if (*program* ≡ *ctangle*) {
    if ((*C_file* ← *fopen*(*C_file_name*, "wb")) ≡ Λ) *fatal*("!␣Cannot␣open␣output␣file␣", *C_file_name*);
  }
  else {
    if ((*tex_file* ← *fopen*(*tex_file_name*, "wb")) ≡ Λ)
      fatal("!␣Cannot␣open␣output␣file␣", *tex_file_name*);
  }
This code is used in section 20.

85. Index.

⟨ Common code for CWEAVE and CTANGLE 2, 4, 5, 6, 8, 9, 11, 13, 14 ⟩   Used in section 1.
⟨ Complain about argument length 82 ⟩   Used in sections 77, 78, and 79.
⟨ Compute the hash code *h* 49 ⟩   Used in section 48.
⟨ Compute the name location *p* 50 ⟩   Used in section 48.
⟨ Enter a new name into the table at position *p* 51 ⟩   Used in section 48.
⟨ Global variables 18, 19, 21, 22, 25, 26, 37, 43, 44, 46, 65, 73, 83 ⟩   Used in section 1.
⟨ Handle flag argument 80 ⟩   Used in section 75.
⟨ If no match found, add new name to tree 61 ⟩   Used in section 59.
⟨ If one match found, check for compatibility and return match 62 ⟩   Used in section 59.
⟨ If the current line starts with @y, report any discrepancies and **return** 34 ⟩   Used in section 32.
⟨ Include files 3 ⟩   Used in section 1.
⟨ Initialize pointers 45, 47 ⟩   Used in section 20.
⟨ Look for matches for new name among shortest prefixes, complaining if more than one is found 60 ⟩   Used
        in section 59.
⟨ Make *change_file_name* 78 ⟩   Used in section 75.
⟨ Make *web_file_name*, *tex_file_name*, and *C_file_name* 77 ⟩   Used in section 75.
⟨ Move *buffer* and *limit* to *change_buffer* and *change_limit* 31 ⟩   Used in sections 27 and 32.
⟨ Open input files 36 ⟩   Used in section 35.
⟨ Override *tex_file_name* and *C_file_name* 79 ⟩   Used in section 75.
⟨ Predeclaration of procedures 7, 10, 12, 15, 24, 28, 33, 55, 64, 76 ⟩   Used in section 1.
⟨ Print error location based on input buffer 67 ⟩   Used in section 66.
⟨ Print the job *history* 69 ⟩   Used in section 68.
⟨ Print usage error message and quit 81 ⟩   Used in section 75.
⟨ Read from *change_file* and maybe turn off *changing* 41 ⟩   Used in section 38.
⟨ Read from *cur_file* and maybe turn on *changing* 40 ⟩   Used in section 38.
⟨ Scan arguments and open output files 84 ⟩   Used in section 20.
⟨ Set the default options common to CTANGLE and CWEAVE 74 ⟩   Used in section 20.
⟨ Skip over comment lines in the change file; **return** if end of file 29 ⟩   Used in section 27.
⟨ Skip to the next nonblank line; **return** if end of file 30 ⟩   Used in section 27.
⟨ Try to open include file, abort push if unsuccessful, go to *restart* 39 ⟩   Used in section 38.
